Problem & Solution

Terminal-Based AI Coding Agent

AI coding tools run model-generated code and edit real files — the hard part is doing that *safely*.

A natural-language agent that writes, runs, and refactors code, with sandboxing and validation built in.

Architecture

How it works: Reason → Act → Observe

User request → agent reasons → calls a tool → observes the result → repeats

Tools: file read/write · code search · **validator** → **Docker sandbox** · git

Guardrails: AST validation · container isolation · confirmation gate · snapshots + rollback

Tech Stack & Honest Notes

Built with

Python · Claude API · Docker · pytest · AST ·
Git

Chose Docker over E2B/Daytona for OS-level
isolation I control directly.

Sandbox boundaries and limitations
documented honestly in the README.
